

Modeling barrier discovery

Can satellite data be used to fill data gaps?

Millie Parks, Josh Jones, Peter Jones & Carlos Garcia de Leaniz

This project has received funding from the European Union's Horizon 2020 research and innovation programme under grant agreement No. 101019622.

Free Flow Conference 15-17 April 2024

Swansea University
Prifysgol Abertawe

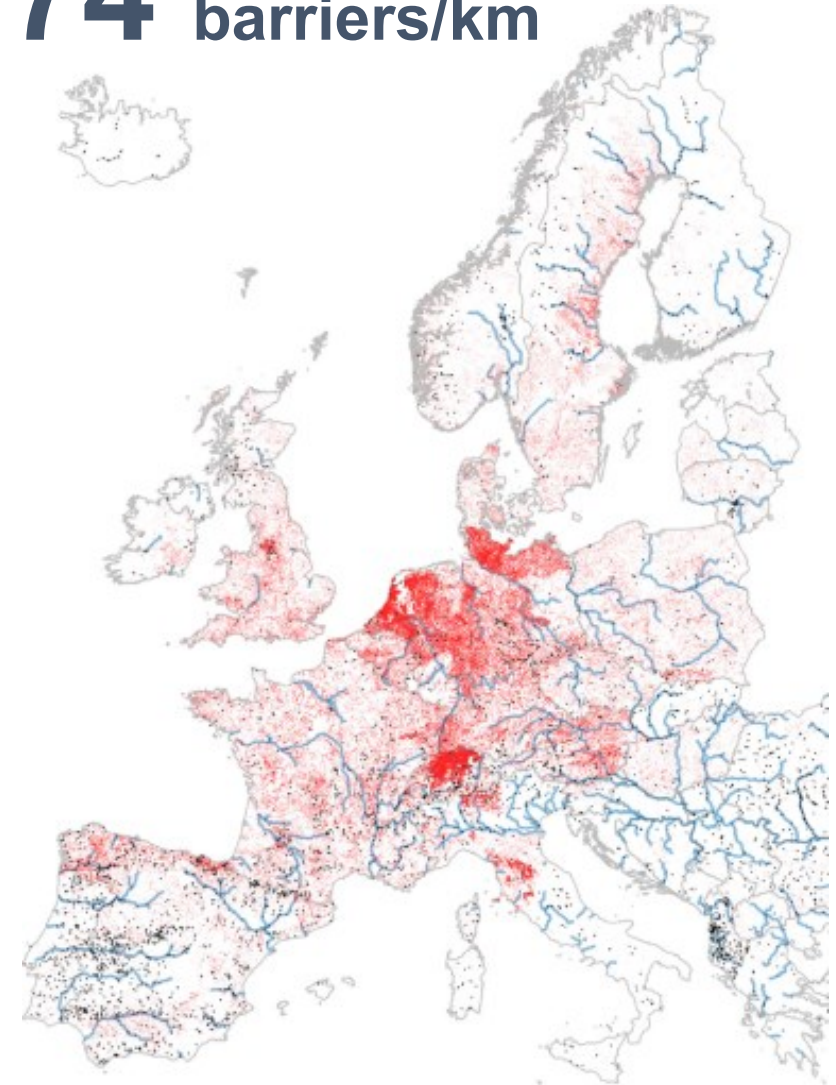

The problem

+1.2M barriers

Goal of **+25K** of
free-flowing rivers
in EU by 2030

European Barrier Density

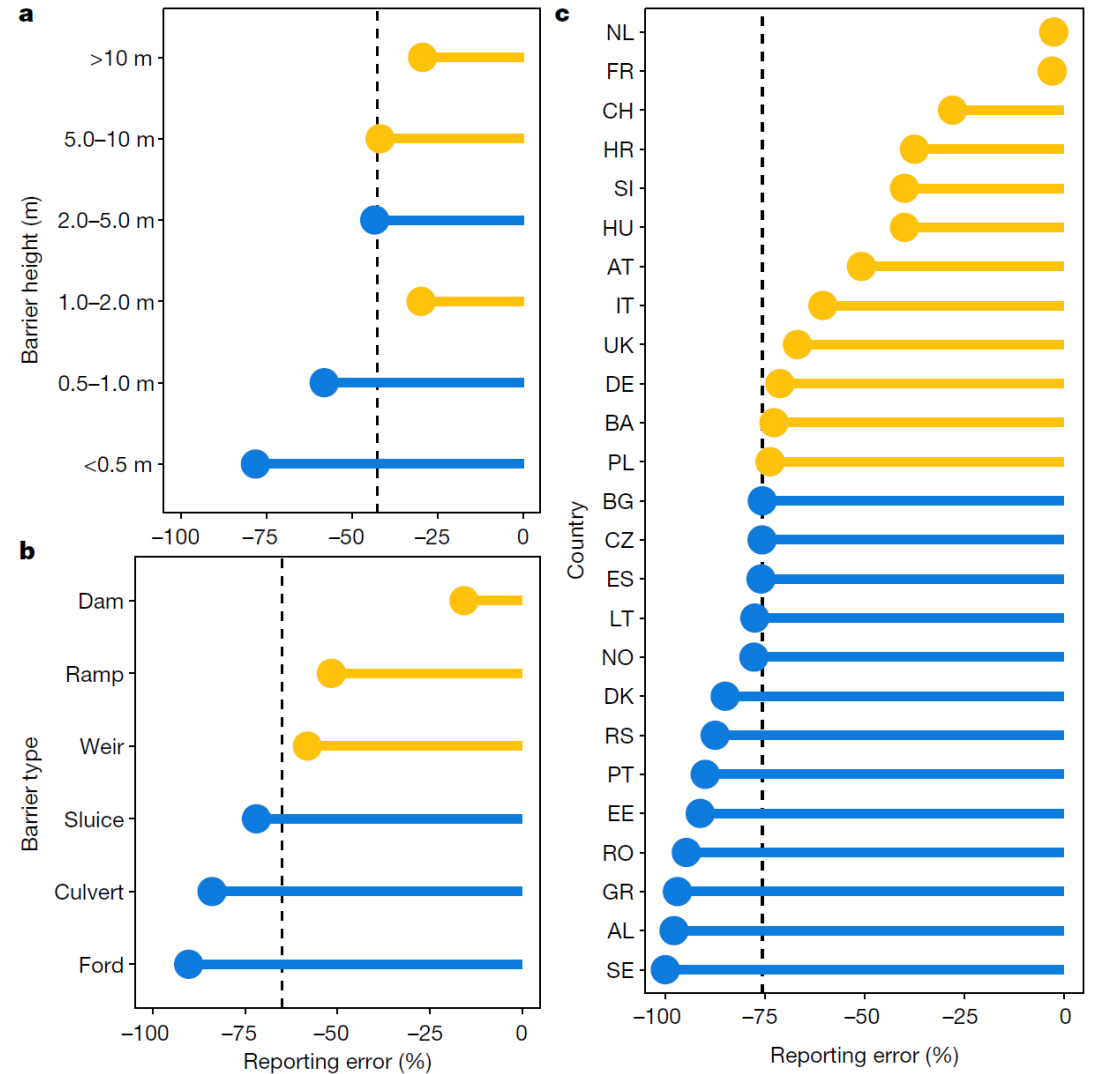

0.74 barriers/km

The problem

Half of the barriers are missing....

Complete walkover surveys are expensive & time consuming

It would take
two people walking
356 yrs
to locate all missing
barriers in Europe*

*or 1 year for a small battalion of 800 people to cover 1.3M km of river network @ 10km/day

It would take
two people walking
356 yrs
to locate all missing
barriers in Europe*

not gonna
happen

*or 1 year for a small battalion of 800 people to cover 1.3M km of river network @ 10km/day

So what are the alternatives...?

1. Remote sensing

2. ML modeling

3....or even better **BOTH**

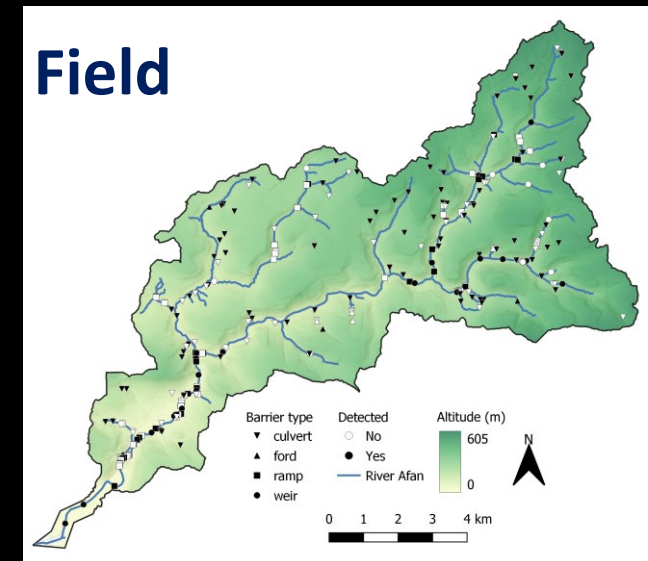

Random Forest

Our study

1. Cross-referenced 468 known barriers (incl a complete walkover) with Google Earth
2. Used ML to model barrier detection (LR, RF, Boosted Trees)
3. Which barriers are detected? which barriers are missing?

R. Afan - Complete survey

GE Detection*

No barrier could be detected from satellite images (>2Km altitude)

but some could be detected from aerial photos (<500m altitude)

*Google Earth stitches together satellite & aerial images

Eye altitude

2km

1km

500m

200m

Field

Culvert

Expense

National Atlas
41 barriers

14%

Google Earth
126 barriers

44%

Walkover
289 barriers

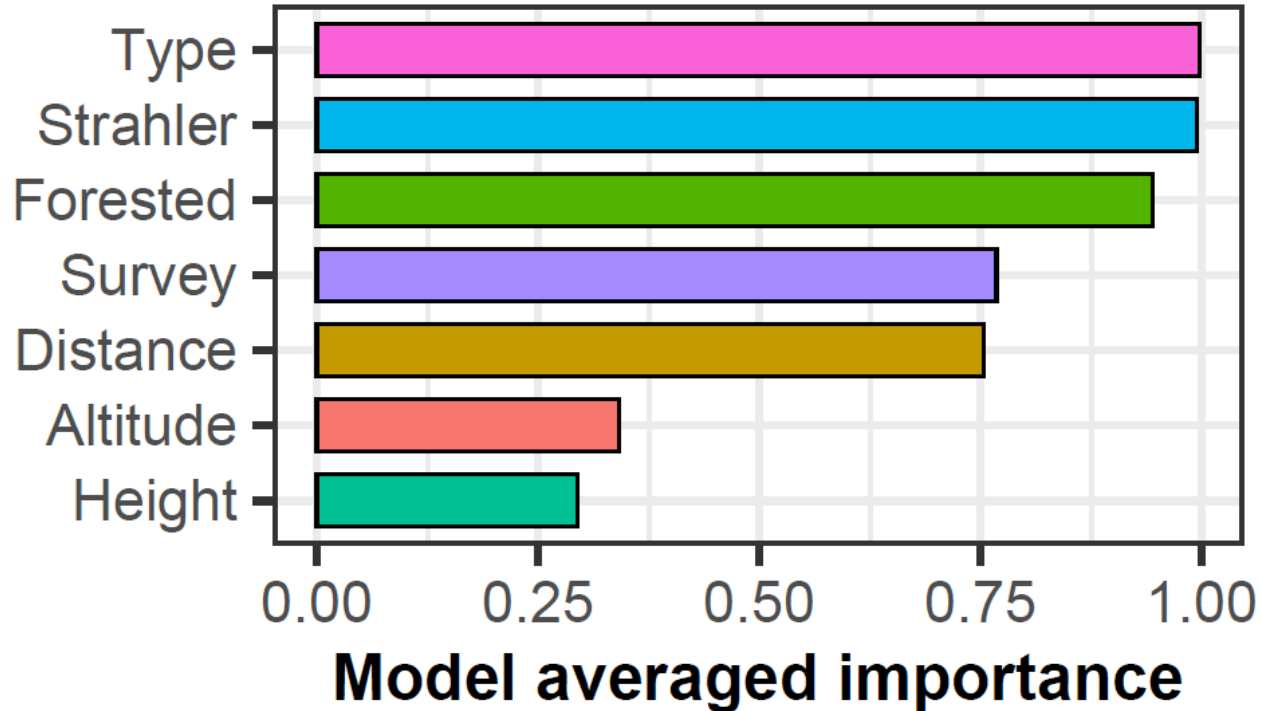

100%

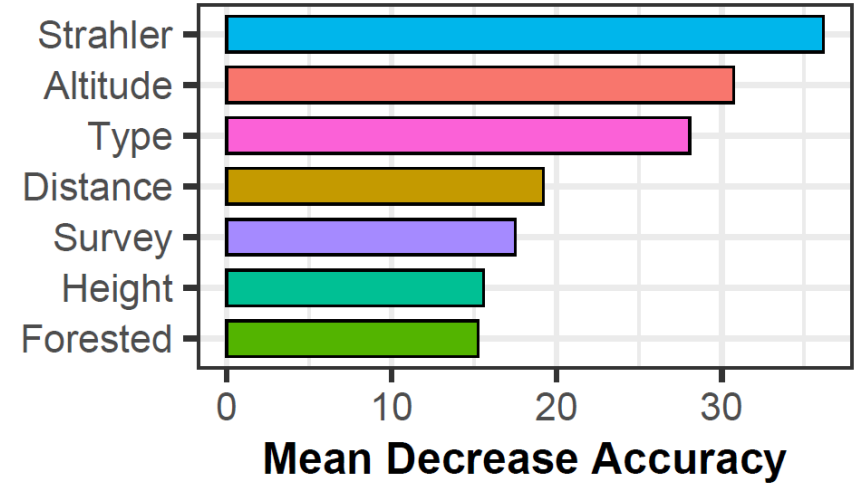

Accuracy

What determines detection?

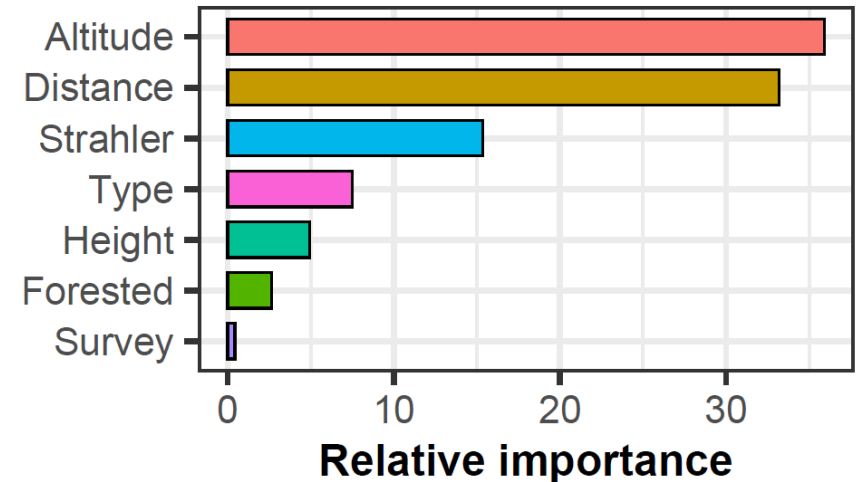

Logistic Regression (AUC = 0.62)

Random Forest (AUC = 0.57)

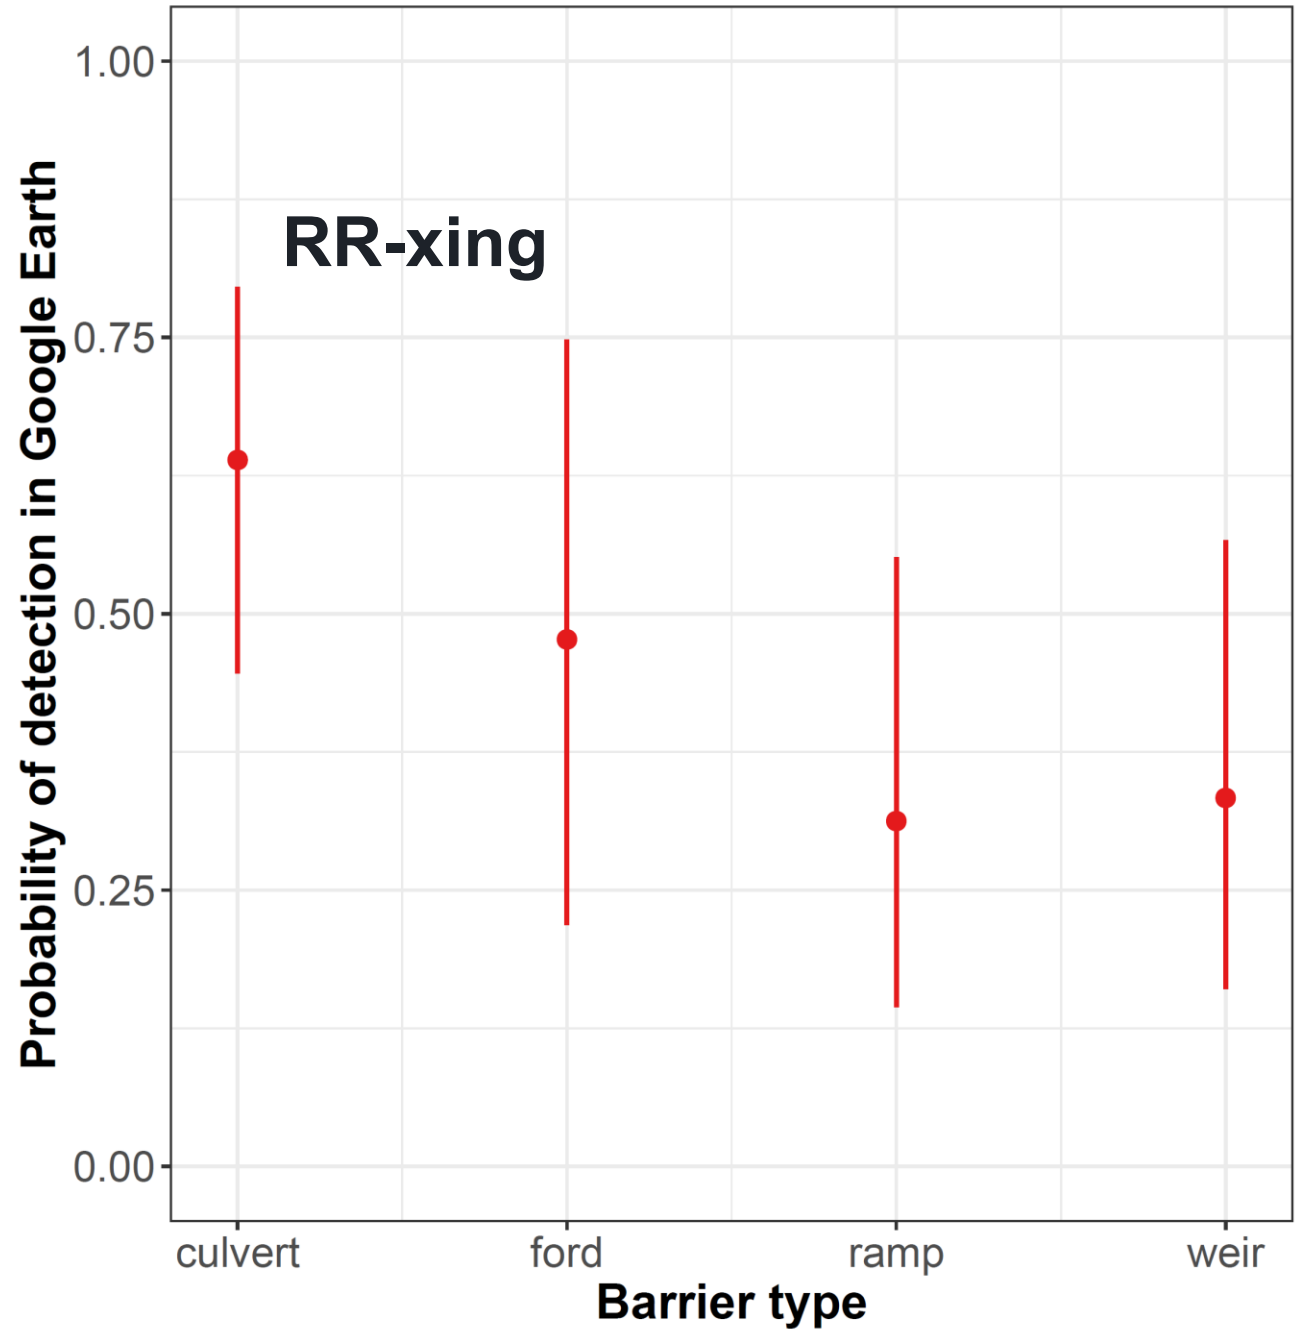

Boosted Trees (AUC = 0.86)

Barrier type

$P < 0.001$

Barriers are easier to detect at river-road crossings

Field

Google Earth

Undetected

Culvert
 $pd = 0.63$

Detected

Field

Google Earth

 $pd = 0.34$

Detected

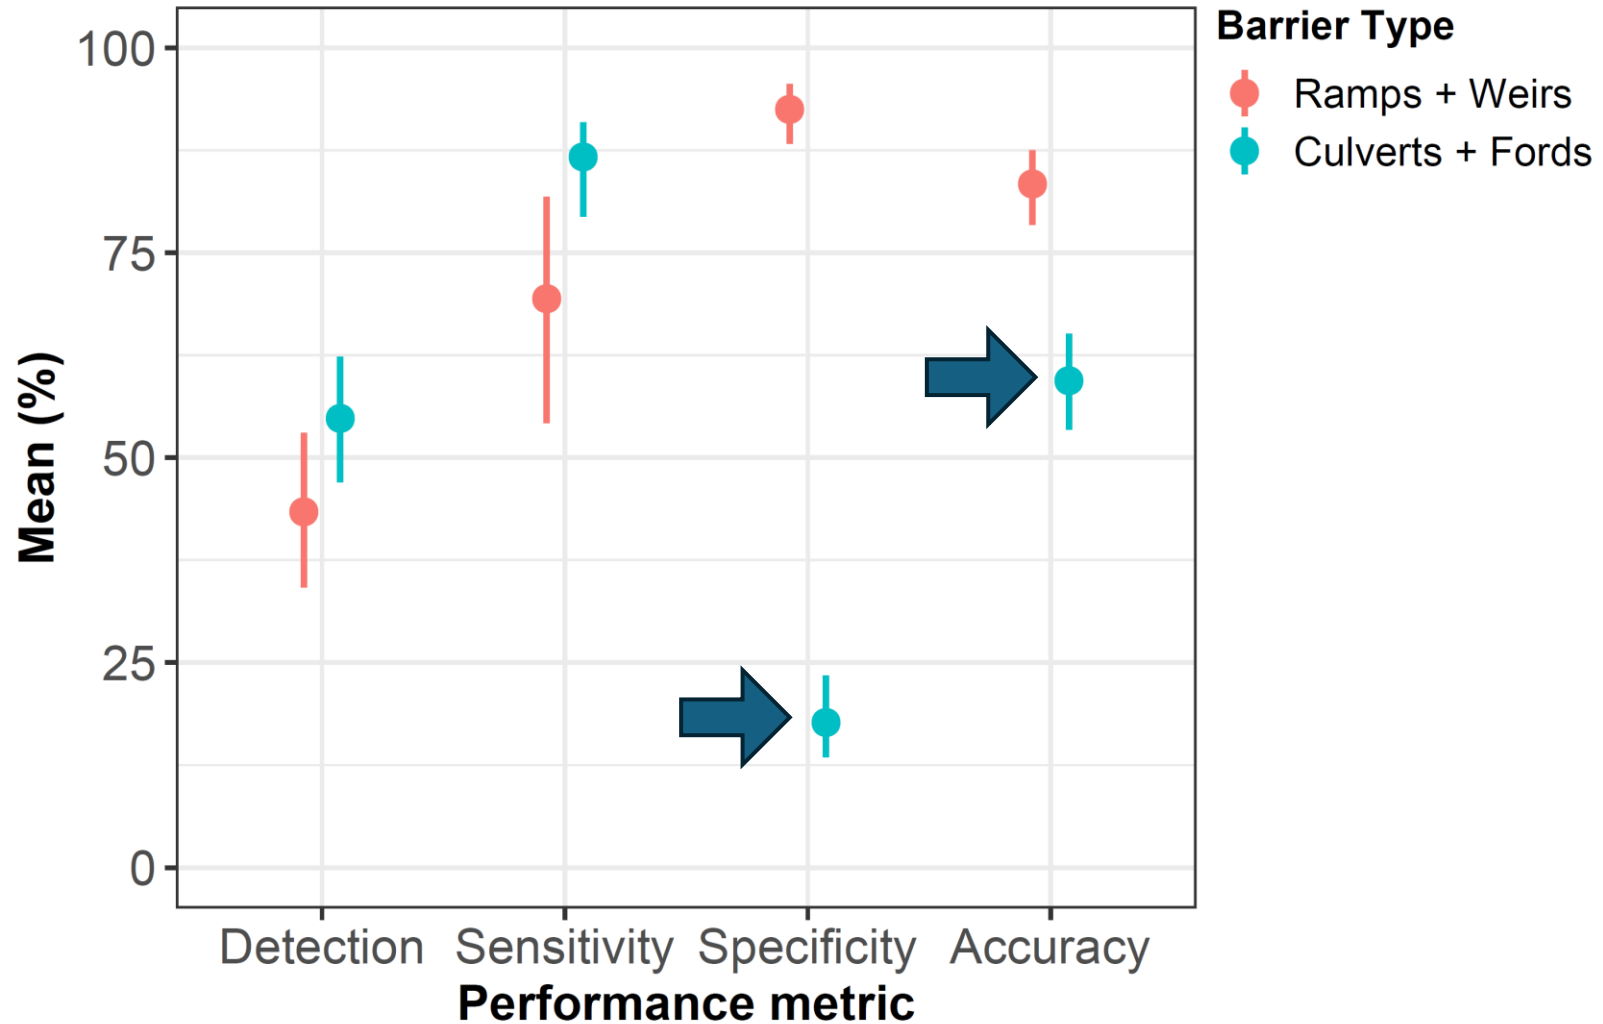

Remote detection metrics

Barriers at RR Xings
are easier to detect
remotely but....

1. Low specificity

2. Poor accuracy

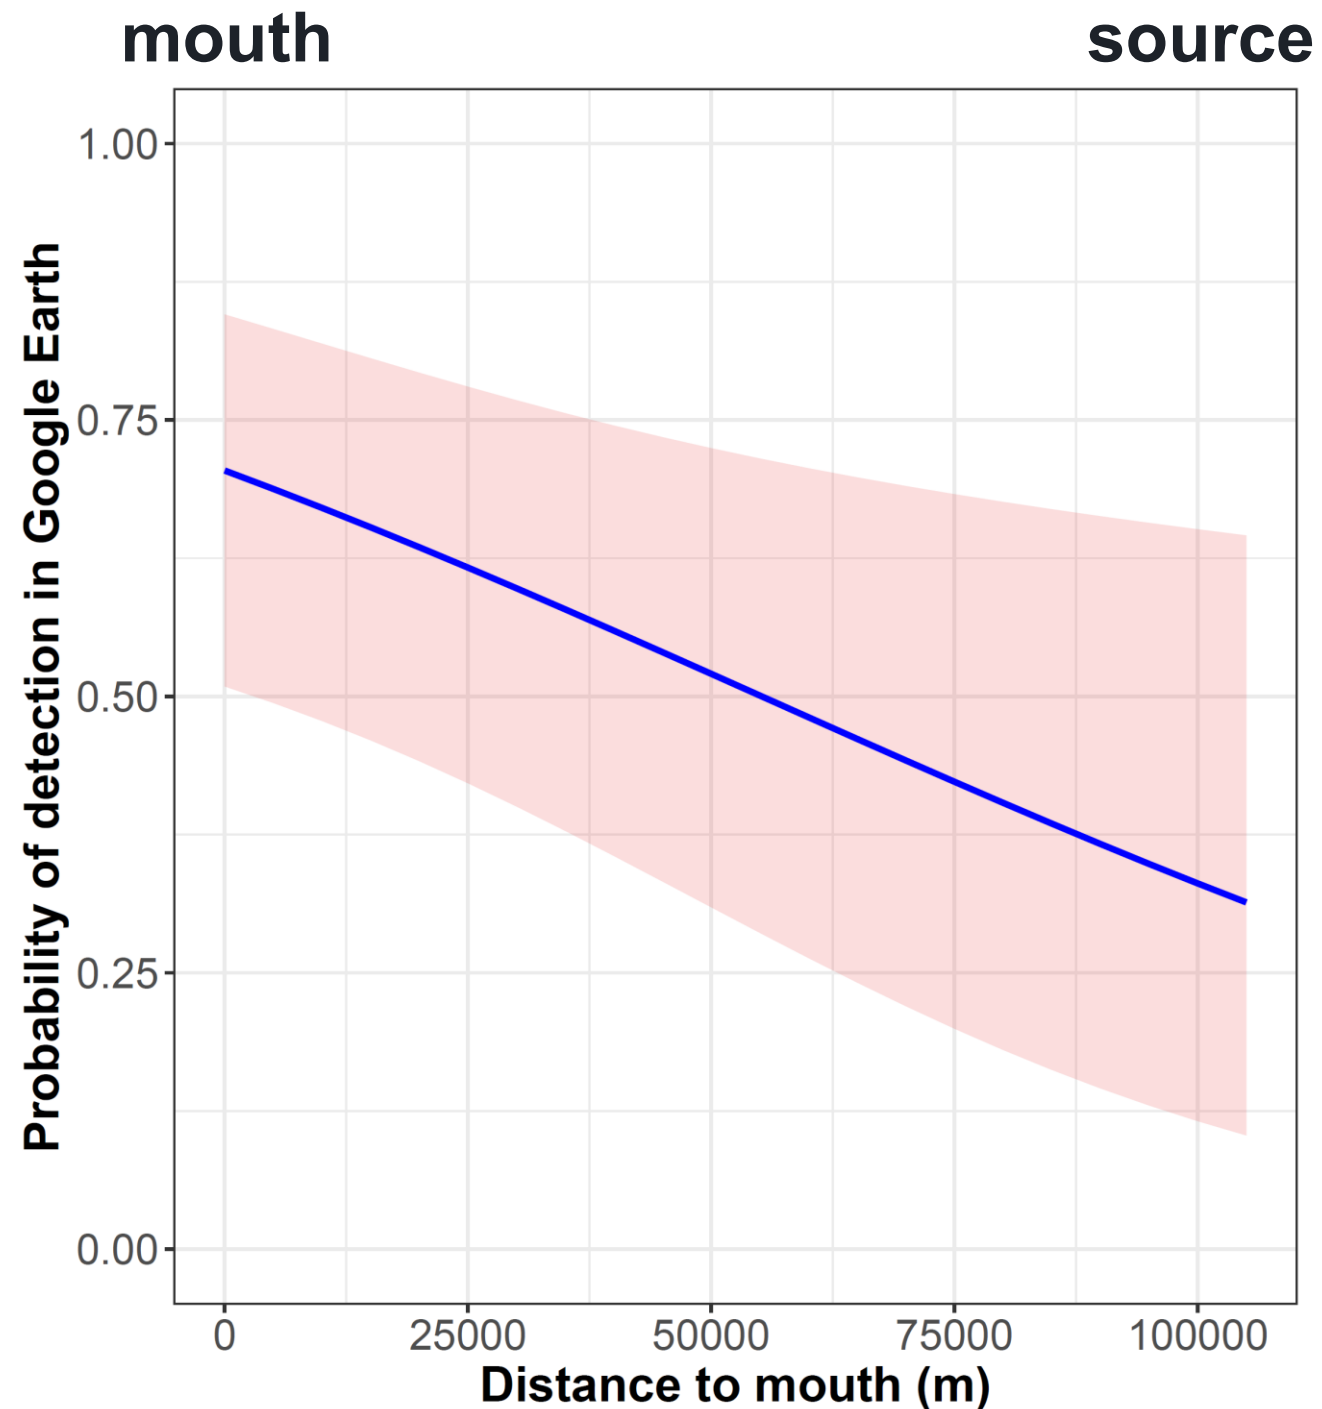

Distance to river mouth

$P = 0.02$

Barriers are harder to detect in the head waters

Every 10 km one moves upstream reduces p detection by $\sim 3\%$

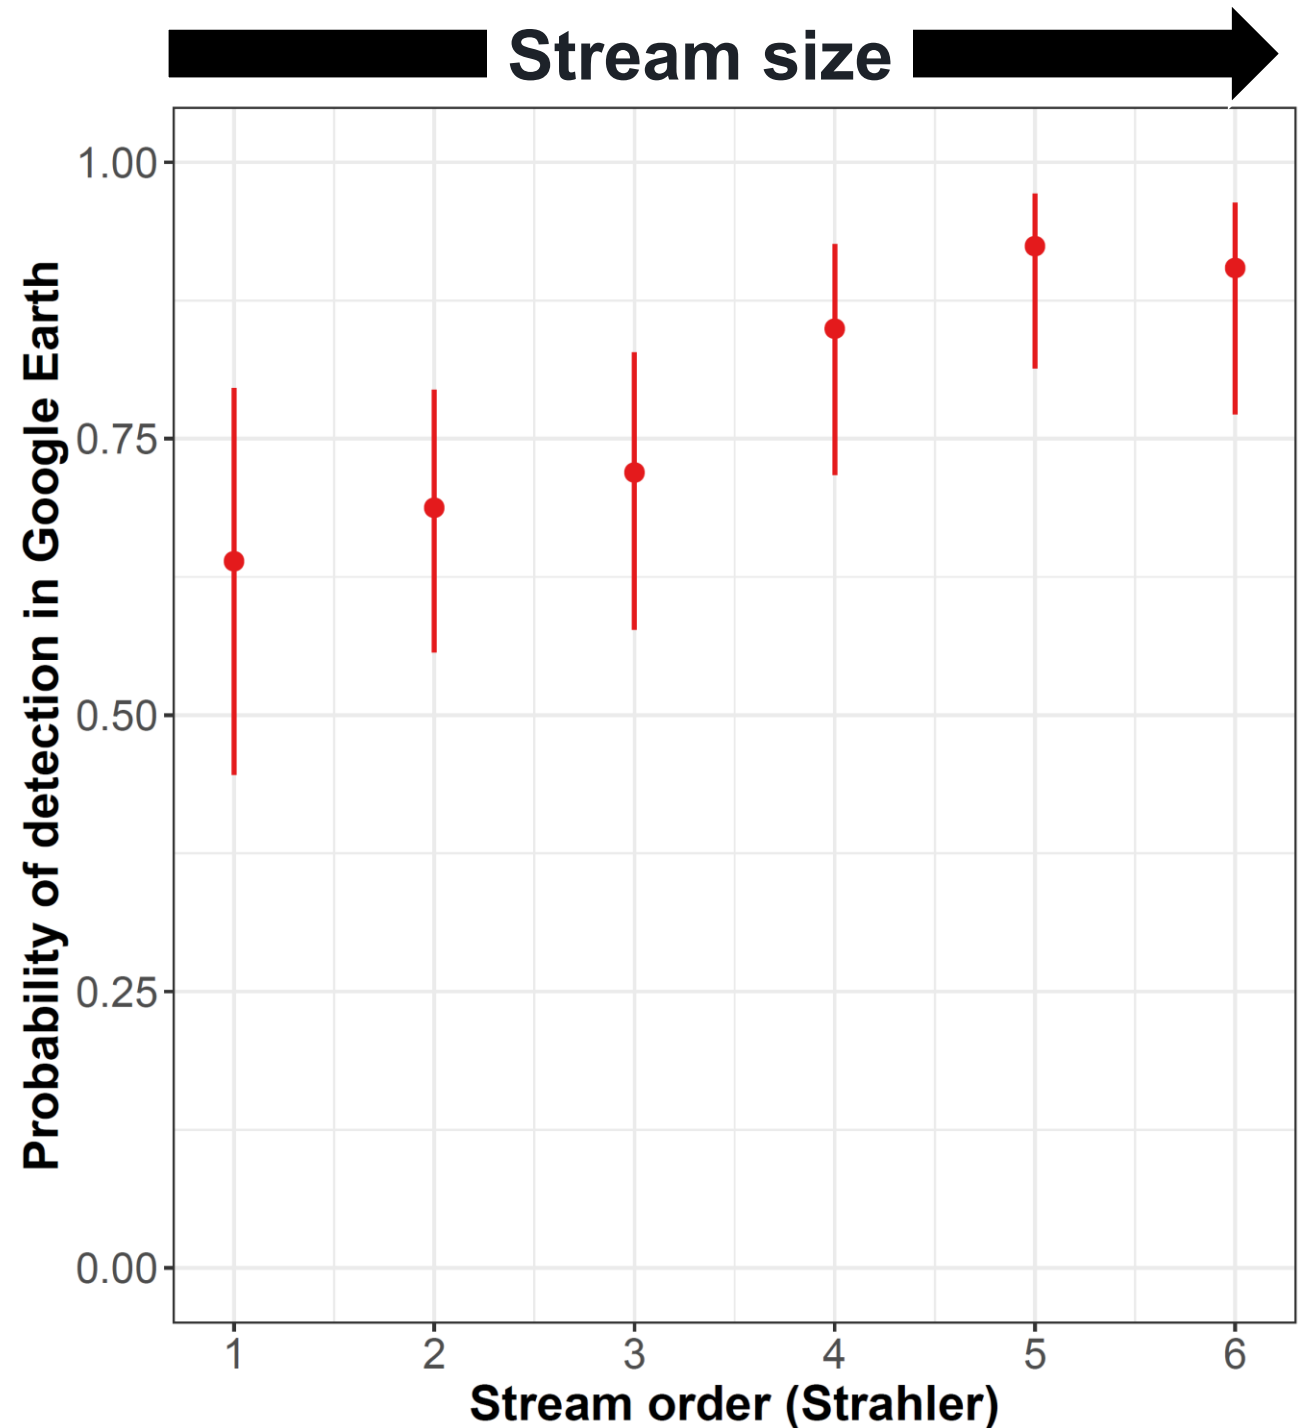

Stream order

$P < 0.001$

Barriers are harder to detect in small rivers

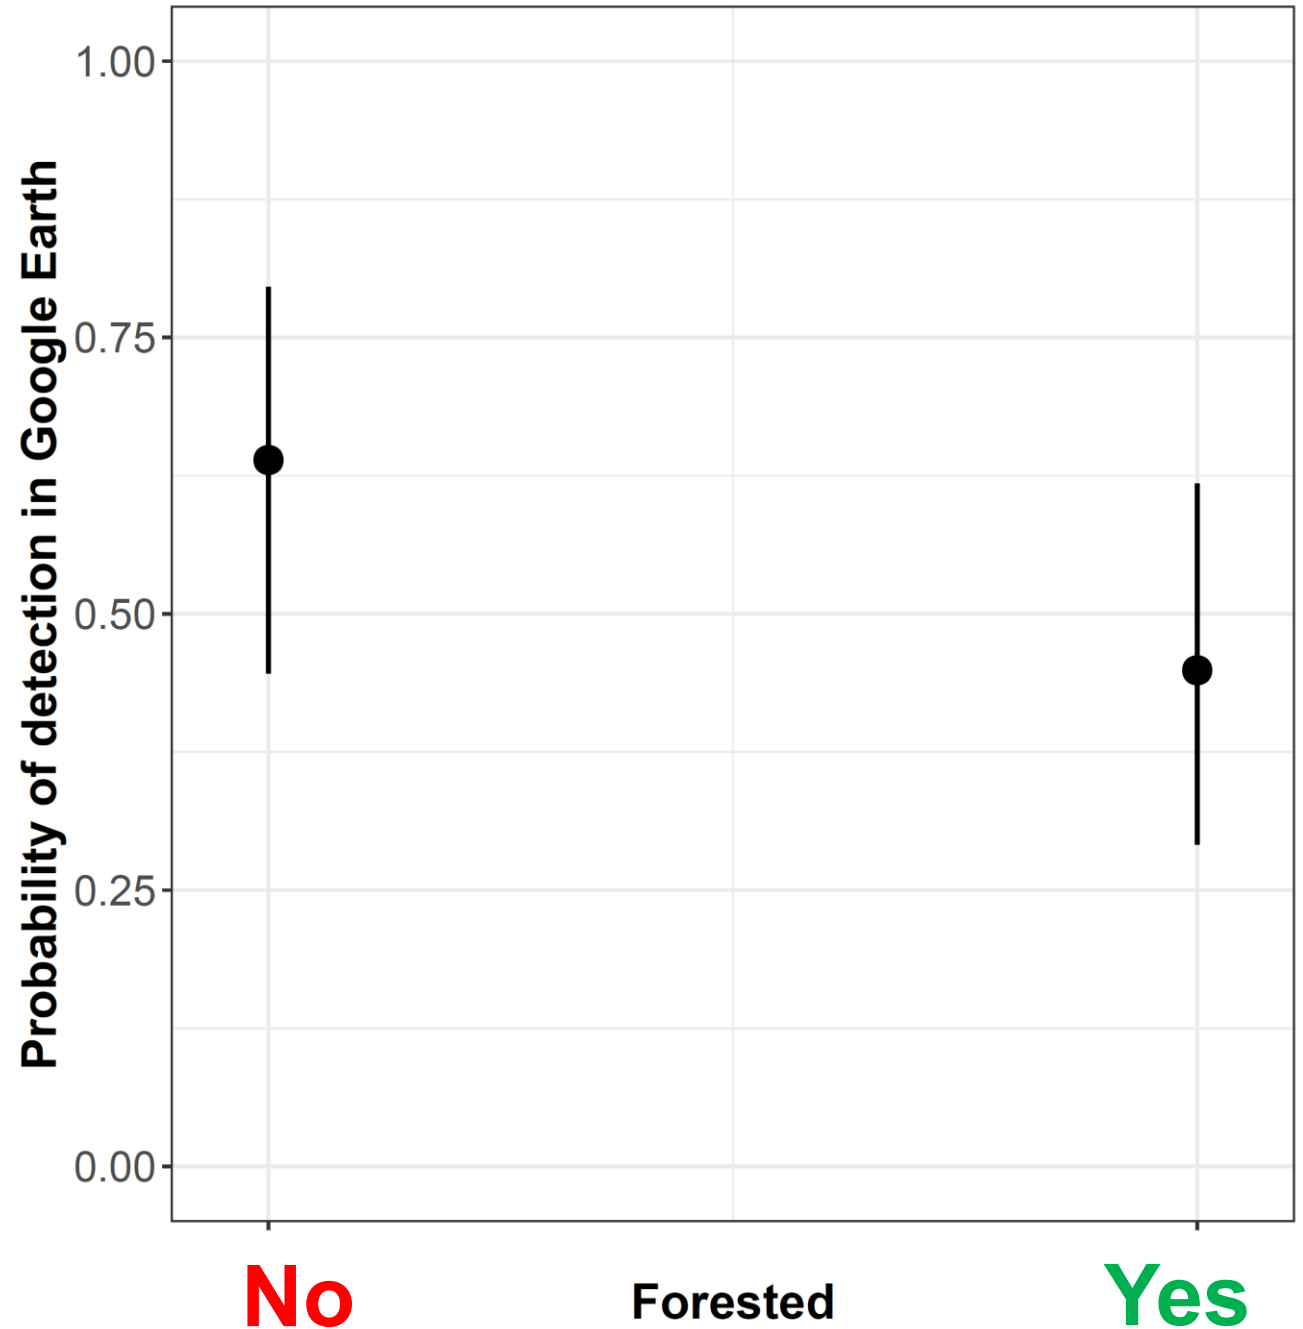

Every unit decrease in stream order reduces p detection by $\sim 4\%$

Forest cover

$P = 0.004$

Barriers are **54%** harder to detect in forested reaches

Conclusions

1. Remote sensing detected **48%** of known barriers
2. ML can predict barrier numbers and most likely locations
3. ...but boots on the ground are needed for efficient barrier prioritization

Thank you
